Acid mine drainage (AMD) occurs primarily when the mineral ore pyrite (FeS₂) is exposed to water and oxygen from air, producing soluble iron and sulfuric acid. One reason that pyrite is important in AMD generation is that it forms under a variety of conditions and is widespread in different rock types.

Acid mine drainage, acid and metalliferous drainage, or acid rock drainage is the outflow of acidic water from metal mines or coal mines. Acid rock drainage occurs naturally within some environments as part of the rock weathering process but is exacerbated by large-scale earth disturbances characteristic of mining and other large construction activities, usually within rocks containing an abundance of sulfide minerals. Areas where the earth has been disturbed may create acid rock drainage. In ma
