"The Nation has lost sight of its public health goals and has allowed the system of public health to fall into 'disarray'," from *The Future of Public Health*. This startling book contains proposals for ensuring that public health service programs are efficient and effective enough to deal not only with the topics of today, but also with those of tomorrow. In addition, the authors make recommendations for core functions in public health assessment, policy development, and service assurances, and identify the level of government—federal, state, and local—at which these functions would best be handled.

Excerpt from *A Theory of the Causation, and Suggestions for the Prevention of Dysentery: Together With Hypotheses on the Causation, and Views as to the Prevention, of Typhoid, Cholera, Yellow Fever, Remittent, Diphtheria, Typhus, and Other Zymotic Diseases in Man and Animals* I have very little to say to the reader - lay or professional. There is nothing new under the sun. Possibly the views herein submitted come within the spirit and meaning of the saying. Yet it will be found that, if they are not new, they have at least been some time in abeyance. Or it may be they are not true. They are startling enough to look unsound; and their consequences, if sound, are so stupendous, that I can hardly bring myself to believe there is not some fatal error, somewhere, in the induction. At the present moment, a successful attempt to unravel the causation, and to indicate means for the prevention, of so many of the most deadly plagues of the world, seems highly improbable, even if it be not regarded as almost an impossibility. I am fully conscious of the distrust with which propositions, having an air of such extreme incredibility, may be at first received. I can conceive they will meet with a hearty opposition. I am prepared to see them rather roughly handled. Yet as I am myself unable to detect any flaw in the reasoning, I send them forth for others to examine. They may, at all events indirectly, if not directly, serve some useful purpose. Whilst, however, the greater number of these views are, admittedly, purely speculative,

and whilst conclusions based upon assumed data may be looked upon with just suspicion; I must lay claim to one substantial discovery - even though the absolute proof be now wanting. I submit that the specific poison of Dysentery has been clearly traced to its source. And, further, that an easy mode of preventing that disease, in any, and in every, country, has been pointed out. If the facts collected, and the inferences drawn from them, do not sustain this, I concede at once that all the propositions as to the causation of other diseases are worthless. Excerpt from *The Journal of Malacology*, Vol. 4 The origin Of the Oyster scare which is so seriously affecting one of our great national industries, that of Oyster culture, appears to be known to few outside the medical profession, and many erroneous Opinions are held with reference to the manner in which the Oysters cause Typhoid Fever. The two diseases which Oysters are believed to have helped to disseminate are Cholera and Typhoid Fever, both of which are now well known to be due to the entrance into the human system of certain organisms - Bacilli - peculiar to these diseases. Cholera cannot arise without the Cholera Bacillus, nor Typhoid Fever without the Typhoid Bacillus. It follows, therefore, that no article of food, including oysters, can cause either of these diseases unless the living bacilli are present. Such being the case, it is nonsense to talk about dead or stale oysters, or decaying food being the cause of either Typhoid Fever or Cholera. The freshest food, the freshest oysters, if contaminated with the specific bacilli, will cause one or other of these diseases, if partaken of by a susceptible person. Excerpt from *Epidemic Man and His Visitations* There are also diseases which shed their morbid products outwardly, and which can come from body to body; as smallpox, typhoid fever, consumption, influenza, cholera, etc., etc. Their products can be the causes of fresh cases, and the parasitic life, if any, which accompanies them can be such a cause, as experiment seems to show. Both infection and contagion are potent here. You can cultivate bacilli out of the body, generations of them, and inserting them into another body produce a disease; whether the first disease that produced the bacilli, or another. You have played with the cause: is the effect the same? In the expectoration from tubercles you have, besides the bacilli, masses of morbid products which are excreted. In Cholera, besides its microbes, you have excretions generally on a large scale. Do the bacilli alone count as causative, or are the entire excreta to be so reckoned? Medicine concentrates attention chiefly, if not entirely, on the micro-organisms. They are the zoological gardens of the microscopes of the pathologists. Excerpt from *How Typhoid Fever Is Spread, And, Notes on Dysentery and Cholera* Food, fingers, and flies offer an alliterative summary of the most common

agents. The one thing upon which we can fix our attention with certainty is the common point of departure. Every germ of typhoid fever, whatever its subsequent history, originates in the body of a typhoid patient and leaves it in the excreta. Every case of typhoid fever is due to the presence of excreta on food or fingers, or in some other place where excreta should not be. Filth is the fundamental condition for the spread of typhoid fever; cleanliness the universal panacea for its eradication. In the 21st century, typhoid fever afflicts more than 21 million people each year, primarily in underdeveloped countries. In the age before sanitation and antibiotics, the infection was even more devastating, crippling entire armies and claiming the lives of both rich and poor. The story of typhoid is in many ways the story of modern medicine itself, with early efforts at treatment and prevention paving the way for our understanding of infectious disease in general. Many sought to understand and control the disease, including Robert Koch and Walter Reed. There were unsung heroes as well: Pierre Louis and William Gerhard, among the first to identify the disease's unique nature; William Budd, whose studies demonstrated its transmission through feces; and Georges Widal, whose test for the disease continues to be used in some areas. This book chronicles the fight against typhoid in the words of these and other medical pioneers, showing how far we have come and how far we have yet to go.

Bacterial Vaccines provides information dealing with vaccination of man against bacterial diseases. This book emphasizes the description, composition, production, and control of the vaccines, as well as vaccine benefits and drawbacks. Organized into 14 chapters, this book contains a description of the etiological agent, particularly with respect to its antigenic composition, and also of the pathogenesis of the disease and the immune mech-

anisms acting against it. The chapters are separated according to the disease they describe, which include diphtheria, tetanus, pertussis, cholera, typhoid fever, shigellosis, *Escherichia coli* infections, meningococcal meningitis, pneumococcal infections, *Haemophilus influenzae* type b infections, *Pseudomonas aeruginosa* infections, gonorrhoea, tuberculosis, and leprosy. This book will provide the reader with a comprehensive survey of vaccination of man against bacterial diseases. It is intended for those involved in vaccine development, production, and control.

Shows how the investigation of local outbreaks of typhoid fever in Victorian Britain led to the emergence of the modern discipline of epidemiology as the leading science of public health

Excerpt from *Maxims of Public Health* The plague, Asiatic cholera. Typhus fever, typhoid fever, diphtheria, scarlatina, yellow fever, small-pox, and some other infectious diseases belong to the same class. The plague, that has frequently decimated mankind, still lingers in an endemic form among the haunts of misery, want, ignorance, and degeneracy of race. It leaps from its lair when unobstructed, and invades the homes of the intelligent and well-to-do classes by infection. It has been declared, by the perversity, the ignorance, the assumption, or some thing worse, of a small but noisy and persistent part of the medical profession, to be non-infectious, and has been left to spread and destroy mankind. It was regarded in former times as a mysterious visitation of Divine Providence, and consequently no measures were taken to arrest its course. Other diseases, now more prevalent, are regarded by many in the same light, and therefore the sanitarian of to-day has to deal with the stubborn apathy of superstition. Typhus fever is nearest of kin to the plague. While it persists in the midst of poverty, filth, and overcrowding in the Old World, it has fortunately never prevailed to any great extent in our American centers of population. Typhoid fever is a member of the same family, and is too well known in all lands. Malignant cholera is a tramp from the same epidemic family, but has fortunately been greatly restricted in its wanderings by a more intelligent quarantine and by increased cleanliness. Yellow fever is first cousin to the plague, and will continue to despoil certain portions of this country till our Southern cities practice sanitation better, and the Federal Government undertakes the duty of preventing its periodic importation. Diphtheria, like the plague, feeds on filth and is propagated by infection. Scarlatina is the more

fervid, but not less malignant, sister of diphtheria. Both knock at our doors with murderous hands, and will not leave till sanitary administration is allowed to enforce with more vigor the isolation and cleanliness taught by advancing sanitary science. Small-pox is the Wandering Jew of the epidemic family but human ingenuity has tamed its destructive spirit with the cunning of vaccination. Here, again, cleanliness and isolation can do the rest. Excerpt from Typhoid Fever and Its Abortive Treatment The objects that are sought to be accomplished by the issuance of this book are: First, to present to the members of the medical profession so much evidence of the truth of the startling declaration that typhoid fever can be aborted as will induce a large number of physicians to

give antiseptic medicine a fair and faithful trial in this disease - the most destructive to adolescent life of all of the acute specific infections - a disease which is both preventable and curable, but which is not only not excluded from, but has been practically invited to invade every community, and has hitherto been allowed to pursue its course uninterrupted by any scientific or efficacious treatment second, to give such explicit directions as will enable all physicians to so intelligently apply the principles of antiseptic medicine to the cure of typhoid fever that they may secure for their patients the least inconvenience and suffering, the shortest duration of illness, and the lowest possible death rate third, and finally, to impress upon the minds of the members of this medical profession the enormity of the crime which is committed by all communities that pour their excrement laden sewage into our fresh water lakes and rivers, in violation of all sanitary principles, of genuine humanness and even of common decency; to the subversion of all efforts at the prophylaxis of typhoid fever, cholera, and other diseases.
