The diesel engine, named after Rudolf Diesel, is an internal combustion engine in which ignition of the fuel is caused by the elevated temperature of the air in the cylinder due to the mechanical compression (adiabatic compression); thus, the diesel engine is a so-called compression-ignition engine (CI engine).

In a diesel engine, ignition is achieved by compression of air alone. A typical compression ratio for a diesel engine is 20:1, compared with 9:1 for a petrol engine. Compressions as great as this heat up the air to a temperature high enough to ignite the fuel spontaneously, with no need of a spark and therefore of an ignition system.

The term turbo-diesel, also written as turbodiesel and turbo diesel, refers to any diesel engine equipped with a turbocharger. As with other engine types, turbocharging a diesel engine can significantly increase its efficiency and power output. Turbocharging of diesel engines began in the 1920s with large marine and stationary engines.

~~Turbo diesel—Wikipedia~~

A diesel engine works by using pistons to compress a mixture of air (containing oxygen) with diesel fuel. When this air is compressed at a ratio of about 15:1 the mixture explodes forcing the piston back up and creating the reciprocating motion. This motion is then converted to rotary motion by the engine's crank shaft.

Fuel is delivered in modern vehicles in two common ways: port fuel injection and direct fuel injection. In a fuel-injected engine, the right amount of fuel is injected individually into each cylinder either right above the intake valve (port fuel injection)

or directly into the cylinder (direct fuel injection).

Rocker Arms. Rocker arms are little levers that touch the lobes, or cams, on the camshaft. When a lobe lifts one end of the rocker, the other end of the rocker presses down on the valve stem, opening the valve to let air in to the combustion chamber or letting exhaust out. It works sort of like a see-saw.
