Human reliability analysis: A critique and review for managers. In running our increasingly complex business systems, formal risk analyses and risk management techniques are becoming more important part to managers: all managers, not just those charged with risk management.

Reliability analysis and risk analysis are two subjects with a great deal of overlap (Aven 2003; Barlow and Proschan 1975; Bedford and Cooke 2001; Høyland and Rausand 1994; Melnick and Everitt 2008).

### **Human Reliability Analysis: a critique and review for managers**

Human reliability analysis (HRA) grew up in the 1960s with the intention of modelling the likelihood and consequences of human error. Initially, it treated the humans as any other component in the system. They could fail and the consequences of their failure were examined by tracing the effects through a fault tree.

Human reliability analyses focus on errors rather than the effects of all forms of human behaviour. Organisation design and culture can correlate failure risks. A research programme to address these issues is suggested. Managers need to question ...

A hierarchical task analysis is conducted on critical activities (i.e. activities with the potential to cause a hazardous event), and starts with the identification of individual

tasks and steps within an activity.

In the early 1990s, criticism over first-generation human reliability analysis (HRA) models, like THERP, SPAR-H, and ASEP, claimed that these models did not have a cognitive architecture capable of dealing with the human information processing.

The human cognitive model not only makes a sound exposition of the generation process and mechanism of human erroneous actions but also improves the accuracy and credibility of human reliability analysis (HRA). Therefore, it helps effectively avoid and prevent human errors in industrial fields.

The term "Human Reliability Assessment" (HRA), human reliability evaluation or analysis, was first introduced in 1962 by Munger et al. [ 1 ] and can be defined as "the probability that a task or job is successfully completed by an individual in a specific state of operation of the system in a minimum required time (if there is time requirements)" [ 2 ].
