The goal of any neural network is to estimate a function f that gives an estimate for a set outputs for a given set of inputs. The above mentioned neural network is called feed-forward because there is no output feedback given back to the input (unlike the recurrent neural network). Input times weights, add Bias and Activate

Introduction. This blog post is the first of a 5-part series which aims to demystify and explain what artificial neural networks (ANN) are and how they learn. It will also showcase a few commercial examples where they have been successfully implemented. As the series is aimed at both technical and non-technical people, the first parts of the series will focus on gaining a conceptual understanding and as we progress the last posts will emphasise more on the mathematics, coding and tools.
