Other human traits have more complex inheritance patterns. Mendelian inheritance refers to the inheritance of traits controlled by a single gene with two alleles, one of which may be dominant to the other. Not many human traits are controlled by a single gene with two alleles, but they are a good starting point for understanding human heredity.

Galtonian Patterns of Inheritance. Mendel's studies focused on dichotomous traits in plants, such as the color of peas (green or yellow) and plant size (tall or dwarf), but many traits have continuous distributions, such as height, weight, and intelligence. Galton was a contemporary of Mendel's who studied the inheritance of continuous characteristics.

When the dominant allele is located on one of the 22 pairs of autosomes (non-sex chromosomes), we refer to its inheritance pattern as autosomal dominant. An example of an autosomal dominant disorder is neurofibromatosis type I, a disease that induces tumor formation within the nervous system that leads to skin and skeletal deformities.

Mendelian inheritance patterns involve genes that directly influence the outcome of an organism's traits and obey Mendel's laws. Most genes in eukaryotic species follow a Mendelian pattern of inheritance. However, there are many that do not. Non-Mendelian inheritance is a general term that refers to any pattern of inheritance in which traits do not segregate in accordance with Mendel's laws.

Some traits seemed to be controlled by complex inheritance patterns. We know now that traits can be controlled by more than one gene, or genetic material may pass down from parent to offspring in different ways than what Mendel predicted with his Law of Segregation.

What is the difference between Mendelian and non-Mendelian inheritance? The Mendelian traits are determined by dominant and recessive alleles of one gene. On the contrary, non-Mendelian traits are not determined by dominant and recessive alleles and can be governed by more than one gene.
